Specimen Collected: 21-Jun-22 15:46

Epithelial Cell Surface Antibody IgG | Received: 22-Jun-22 09:55 Report/Verified: 22-Jun-22 14:32

Procedure	Result	Units	Reference Interval
Epithelial Cell Surface Ab IgG	See Note ^{f1}		

Result Footnotef1: Epithelial Cell Surface Ab IgG
CLINICAL INFORMATION

Mucosal erosions and few scattered eroded lesions on upper body skin. Presumptive diagnosis is pemphigus versus mucous membrane pemphigoid.

Specimen Details

S22-IP0000505 - Serum; Collected: 6/21/2022; Received: 6/22/2022

DIAGNOSTIC INTERPRETATION

Consistent with IgG-variant pemphigus, including pemphigus foliaceus and pemphigus vulgaris

(See Results and Comments including further testing recommendations)

RESULTS

Indirect Immunofluorescence (IIF)

Cell Surface (CS)/Intercellular Substance (ICS) IgG Antibodies

IgG: Positive, titer 1:2,560 (H), monkey esophagus substrate
Positive, titer 1:640 (H), intact human skin substrate

Reference Range:

Negative - Titer less than 1:10

Borderline - Titer 1:10

Positive (H) - Titer greater than 1:10

(H) = high/positive

COMMENTS

Specific

These indirect immunofluorescence test results, demonstrating positive serum IgG cell surface (CS), also known as intercellular substance (ICS) antibodies, reactive with both monkey esophagus substrate and intact human skin substrate, support the diagnosis of pemphigus vulgaris or pemphigus foliaceus or another IgG-variant pemphigus. Pemphigus foliaceus and pemphigus vulgaris can be distinguished by the predominance of IgG desmoglein 1 or IgG desmoglein 3 antibodies, respectively, determined by enzyme-linked immunosorbent assay (ELISA). Another consideration is that, although IgA CS/ICS antibodies characterize IgA pemphigus, they also may be observed in some pemphigus variants along with positive IgG CS/ICS antibodies.

Further ELISA testing for IgG desmoglein 1 and IgG desmoglein 3 antibody levels is recommended and can be accomplished on this specimen by contacting ARUP Client Services, 1-800-242-2787, option 2, with add-on test request for:

f1: Epithelial Cell Surface Ab IgG
 - Desmoglein 1 and Desmoglein 3 (Pemphigus) Antibodies,
 IgG by ELISA (ARUP test number 0090649),
 with or without additional indirect immunofluorescence testing to determine if IgA CS/ICS antibodies also
 are expressed with add-on test request for:
 - Pemphigus Antibodies, IgA by IIF (ARUP test
 number 0092106).

IgG cell surface antibody titers and IgG desmoglein antibody levels correlate with disease activity in
 IgG-variant pemphigus, including pemphigus foliaceus and pemphigus vulgaris. Of note, cell surface
 reactivity by indirect immunofluorescence may be observed transiently and/or nonspecifically in normal
 individuals, and in patients with infections, drug reactions, and other mucocutaneous disorders. Clinical
 correlation is needed, including treatment status and with direct immunofluorescence findings on a
 biopsy specimen. Monitoring antibody levels by ELISAs as well as antibody profiles by indirect
 immunofluorescence may aid in assessing disease expression and activity, including response to therapy.

General

Greater than 80 percent of patients with pemphigus have positive epithelial cell surface (CS) antibodies,
 also known as intercellular substance (ICS) antibodies, in their sera identified by indirect
 immunofluorescence. Serum antibody titers correlate with disease activity, and CS/ICS antibodies may be
 in low titer or negative in patients whose disease activity is minimal and/or under therapeutic control.
 Cell surface antibodies are implicated in the pathophysiology of pemphigus. However, cell surface
 reactivity may be observed transiently and/or nonspecifically in normal individuals and in patients with
 infections, drug reactions, and other mucocutaneous disorders, including other immunobullous diseases,
 generally in low titer. IgG CS/ICS antibodies characteristically are positive by indirect
 immunofluorescence in IgG pemphigus variants, including pemphigus foliaceus and pemphigus vulgaris, and
 IgA CS/ICS antibodies are positive by indirect immunofluorescence in IgA pemphigus, although IgA CS/ICS
 antibodies may be observed in some pemphigus variants along with positive IgG CS/ICS antibodies.
 Approximately 40 percent of patients with nonclassical IgG/IgA pemphigus have an underlying systemic
 disease when diagnosed, malignancy being the most common.

Pathogenic IgG CS/ICS antibodies in serum from patients with pemphigus bind to desmogleins, which are
 calcium-dependent adhesion molecules in desmosomes; such antibodies are detected by enzyme-linked
 immunosorbent assay (ELISA) testing. Specific reactivity to the type of desmoglein may be helpful in
 determining pemphigus subtypes; the IgG desmoglein 1 antibody level is increased in patients with
 pemphigus foliaceus, and the IgG desmoglein 3 antibody level, with or without an increased IgG desmoglein
 1 antibody level, is predominantly increased in patients with pemphigus vulgaris. Overlapping expression
 with autoantibodies to both desmogleins 1 and 3 typically is associated clinically with both mucosal and
 skin lesions. ELISA testing for IgG desmoglein 1 and IgG desmoglein 3 antibodies is highly sensitive,
 with greater than 90 percent of patients with pemphigus showing increased levels of one or both
 antibodies.

TESTING METHODS

Indirect Immunofluorescence (IIF)

IgG Epithelial Cell Surface (CS)/Intercellular Substance (ICS) Antibodies

Patient serum is progressively diluted in calcium-containing buffer beginning at 1:10 in three two-fold
 screening dilutions, layered on sections of intact normal human skin and monkey esophagus substrates, and
 stained with fluorescein isothiocyanate (FITC)-conjugated antibody to IgG. When positive, the serum is
 further diluted in two-fold reductions to the limiting dilution of antibody detection or to a maximum
 dilution of 1:40,960. The limiting-dilution, end-point titer is reported for each substrate. This IIF
 testing was developed and its performance characteristics determined by the Immunodermatology Laboratory
